

NATIONAL HURRICANE CENTER TROPICAL CYCLONE REPORT

HURRICANE HENRI

(AL082021)

15–23 August 2021

Richard J. Pasch, Robbie Berg, and Andrew B. Hagen National Hurricane Center 28 April 2022¹

GOES-16 VISIBLE SATELLITE IMAGE OF HURRICANE HENRI AT 2100 UTC 21 AUGUST 2021. IMAGE COURTESY OF NAVAL REASEARCH LABORATORY

Henri was a category 1 hurricane (on the Saffir-Simpson Hurricane Wind Scale) that followed an unusual track over the western Atlantic, eventually making landfall in Rhode Island as a 55-kt tropical storm. Henri caused extensive flooding in parts of the northeastern United States.

¹ Original report dated 25 January 2022. This version updates the characterization of the rip current fatalities that occurred in North Carolina on 18 August to indicate that they were not associated with Henri.

Hurricane Henri

15-23 AUGUST 2021

SYNOPTIC HISTORY

Henri was of non-tropical origin. A cluster of thunderstorms associated with a mid-level disturbance moved off the U.S. Mid-Atlantic coast late on 11 August and early on 12 August. Deep convection associated with this system temporarily diminished, but its thunderstorms increased early on 13 August a few hundred n mi southeast of southeastern Massachusetts. The disturbance generated a weak surface trough a few hundred n mi north-northeast of Bermuda on 14 August, and this trough evolved into a surface low pressure system by 0000 UTC 15 August, centered a little over 200 n mi north-northeast of Bermuda. While the low moved slowly south-southeastward, deep convection gradually became better organized in a few bands over the southern portion of the circulation. Around 1800 UTC 15 August, the system's convection became sufficiently organized to designate the formation of a tropical depression, centered about 150 n mi northeast of Bermuda. The "best track" chart of the tropical cyclone's path is given in Fig. 1, with the wind and pressure histories shown in Figs. 2 and 3, respectively. The best track positions and intensities are listed in Table 1².

The cyclone moved southward to south-southwestward on the eastern side of a mid-level high pressure area over the western Atlantic, and gradually strengthened into Tropical Storm Henri around 1800 UTC 16 August while centered about 110 n mi southeast of Bermuda. Henri turned southwestward on 17 August while strengthening only slowly, likely due to northerly vertical shear and relatively dry air at mid-tropospheric levels which resulted in a lack of deep convection over the northern part of the circulation. Moving around the southern periphery of the mid-level anticyclone, Henri turned westward and strengthened to an intensity of 60 kt by 1800 UTC 18 August. Under the persistent influence of northerly shear and dry low- to mid-tropospheric air, the storm's intensity leveled off, and slight weakening occurred on 19 August while Henri continued westward. Microwave imagery showed some southward tilt of the vortex with height, as the shear increased even a little more that day.

On 20 August, the shear began to relax while the storm turned northwestward and northward ahead of a mid-tropospheric trough/low just inland of the mid-Atlantic coast. The reduced shear and higher oceanic heat content associated with the Gulf Stream resulted in some slight restrengthening, and by 1200 UTC 21 August Henri became a 65-kt hurricane while centered about 170 n mi southeast of Cape Hatteras, North Carolina. The cyclone accelerated

² A digital record of the complete best track, including wind radii, can be found on line at <u>ftp://ftp.nhc.noaa.gov/atcf</u>. Data for the current year's storms are located in the *btk* directory, while previous years' data are located in the *archive* directory.

north-northeastward on 21–22 August toward the northeast U.S. coast, on the east side of the mid-level low. After moving north of the Gulf Stream, Henri weakened below hurricane strength by 1200 UTC 22 August, and it made landfalls on Block Island and near Westerly, Rhode Island around 1520 and 1615 UTC, respectively, on 22 August as a 55-kt tropical storm. Slowing in forward speed while turning westward around the northern part of the mid-level low, the system weakened rapidly over southern New England, and Henri was reduced to a tropical depression over western Connecticut by 0000 UTC 23 August. After moving into southeastern New York, the weakening cyclone looped back into Connecticut late on 23 August, where it degenerated into a remnant low. The system then headed east-northeastward over Rhode Island and southeastern Massachusetts on 24 August, and moved back over the western Atlantic where it dissipated late that day.

METEOROLOGICAL STATISTICS

Observations in Henri (Figs. 2 and 3) include subjective satellite-based Dvorak technique intensity estimates from the Tropical Analysis and Forecast Branch (TAFB) and the Satellite Analysis Branch (SAB), objective Advanced Dvorak Technique (ADT) estimates and Satellite Consensus (SATCON) estimates from the Cooperative Institute for Meteorological Satellite Studies/University of Wisconsin-Madison. Observations also include flight-level, stepped frequency microwave radiometer (SFMR), and dropwindsonde observations from WC-130 flights of the 53rd Weather Reconnaissance Squadron of the U.S. Air Force Reserve Command and WD-P3 aircraft of the NOAA Aircraft Operations Center. There were 19 center fixes in Henri made by the Air Force C130s, and 5 made by the NOAA P3s. There were also 4 synoptic surveillance flights performed by the NOAA G-IV aircraft.

Data and imagery from NOAA polar-orbiting satellites including the Advanced Microwave Sounding Unit (AMSU), the NASA Global Precipitation Mission (GPM), the European Space Agency's Advanced Scatterometer (ASCAT), and Defense Meteorological Satellite Program (DMSP) satellites, among others, were also useful in constructing the best track of Henri.

Ship reports of winds of tropical storm force associated with Henri are given in Table 2, and selected surface observations from land stations and data buoys are given in Table 3.

Winds and Pressure

Henri's maximum intensity of 65 kt is based on a blend of flight-level winds and SFMRobserved surface winds from Air Force Reserve Unit and NOAA Hurricane Hunter aircraft. The peak surface-adjusted flight-level wind was 74 kt around 1300 UTC 21 August while the maximum observed surface wind around the same time was 55 kt. Later, at 2345 UTC on the 21st, the maximum surface-adjusted flight-level wind was 66 kt and the peak surface wind was 66 kt.

The 55-kt landfall intensity of Henri in Rhode Island is based on 2 surface observations, one from Great Gull Island, New York, of a 1-minute wind of 56 kt at 1600 UTC 22 August, and another from Point Judith, Rhode Island, of a 1-minute wind of 53 kt at 1522 UTC 22 August. Both

of these observations were at an elevation of 16 m, which reduce to 10-m winds of 53 kt and 50 kt at Great Gull and Point Judith, respectively, using an exponential wind reduction formula.

Tropical-storm-force winds associated with Henri occurred mainly in Rhode Island, southern Connecticut, extreme southern Massachusetts, and Long Island. Wind gusts to 61 kt and 60 kt were measured at Point Judith and Great Gull Island, respectively. A sustained wind of 38 kt with a gust to 49 kt was observed at Quonset Point, Rhode Island. Sustained winds of 38 kt with gusts to 49 kt were also measured at the U.S. Coast Guard Academy in New London, Connecticut. A wind gust to 44 kt was observed at the Wall Street Heliport in downtown New York City. Sustained winds of 38 kt and gusts to 45 kt were observed at Baiting Hollow in Long Island, New York. A sustained wind of 45 kt with a gust to 57 kt was measured at Buzzard's Bay, Massachusetts, but this was a significantly elevated (25 m) observing site.

The minimum central pressure of Henri, 986 mb, is based on a dropsonde measurement at 0658 UTC 22 August of 987 mb with 10-kt winds at the surface.

Henri's landfall pressure of 987 mb on Block Island, Rhode Island is based on a surface observation of 987.1 mb from Block Island. The landfall pressure of 988 mb at Westerly, Rhode Island is based on an eye dropsonde pressure of 990 mb with 21-kt winds at 1523 UTC 22 August.

Henri is the strongest tropical cyclone to pass over New England since Tropical Storm Bertha in July of 1996. The last hurricane to make landfall in New England was Bob in August of 1991.

Storm Surge³

The highest measured storm surges from Henri were 2.57 ft above normal tide levels at a United States Geological Survey (USGS) tide gauge at Riverhead, New York, and 2.46 ft above normal tide levels at a National Ocean Service (NOS) tide gauge at Quonset Point, Rhode Island. Higher surges likely occurred between *in situ* water level gauges.

Combined with the tides, Henri's surge resulted in inundation levels as high as 2 to 4 ft above ground level along the north shore of Long Island and the coast of Connecticut (Table 3, Fig. 4). The highest water level recorded by a coastal gauge was by a USGS wave height sensor near the village of Greenport on the North Fork of Long Island, which measured a converted wave-filtered water level of 3.1 ft above Mean Higher High Water (MHHW). A USGS wave height sensor near Greenwich, Connecticut, measured a converted wave-filtered water level of 2.1 ft

³ Several terms are used to describe water levels due to a storm. **Storm surge** is defined as the abnormal rise of water generated by a storm, over and above the predicted astronomical tide, and is expressed in terms of height above normal tide levels. Because storm surge represents the deviation from normal water levels, it is not referenced to a vertical datum. **Storm tide** is defined as the water level due to the combination of storm surge and the astronomical tide, and is expressed in terms of height above a vertical datum, i.e. the North American Vertical Datum of 1988 (NAVD88). **Inundation** is the total water level that occurs on normally dry ground as a result of the storm tide, and is expressed in terms of height above ground level. At the coast, normally dry land is roughly defined as areas higher than the normal high tide line, or Mean Higher High Water (MHHW).

MHHW. However, a storm surge simulation hindcast produced by the NHC Storm Surge Unit (not shown) indicated that peak inundation levels up to 4 ft above ground level likely occurred along isolated portions of both the northern and southern shores of Long Island Sound where there were no tide gauges or water level sensors.

Storm surge inundation levels of 1 to 3 ft above ground level occurred elsewhere along the south shore of Long Island and the coasts of Rhode Island and southeastern Massachusetts. Peak water levels measured in these areas include 2.2 ft MHHW near East Hampton, New York; 2.3 ft MHHW near Narragansett, Rhode Island; and 1.7 ft MHHW at several locations in southeastern Massachusetts.

Rainfall and Flooding

The heaviest rains associated with Henri occurred in extreme southeastern New York and northern New Jersey (Table 3, Fig. 5) where rainfall totals ranged from 5 to nearly 10 inches. The highest amount was 9.88 inches which fell in Greenwood Lake, New York. A total of 9.56 inches was recorded in Brooklyn, New York.

Flooding was extensive, particularly in New Jersey, New York, and Connecticut. Helmetta, in central New Jersey, was especially hard hit where some 200 residents had to seek higher ground. A team of police, firefighters and other emergency responders rescued nearly 100 people from floods in Newark, New Jersey. Waist-deep flooding was reported in Brooklyn, New York. Considerable disruption of roadways due to flooding was noted in the above three states.

Tornadoes

There were 3 tornadoes associated with Henri, in Marlborough, Bolton, and Stow Massachusetts. All of them were small, weak, and short-lived with path widths of 50 m or less and path lengths of 0.75 n mi or less. All were rated EF-0, caused no casualties, and resulted in little or no damage.

CASUALTY AND DAMAGE STATISTICS

Two family members (a 50-year old father and 28-year old son) drowned on 18 August after being caught in a rip current near a pier in Oak Island, North Carolina. However, since it has been determined that the swells associated with the tropical cyclone had not yet reached the coast of North Carolina on that date, these fatalities are not associated with Henri.

Flooding was the most significant impact from Henri's landfall. Wind damage appeared to be mostly downed trees in Rhode Island, Massachusetts, Connecticut, southeastern New York, and New Jersey.

More than 140,000 homes across Connecticut, Rhode Island, Massachusetts and New York were left without power after Henri's passage.

According to the National Centers for Environmental Information, Henri caused an estimated \$700 million in damage in the United States.

FORECAST AND WARNING CRITIQUE

Genesis

Henri's formation was not well predicted. The system from which it formed was not mentioned in the Tropical Weather Outlook (TWO) until just 18 h prior to genesis, with a low (<40%) chance of development (Table 4). The disturbance's formation chances never reached the medium or high categories in the TWO before genesis occurred. Henri's non-tropical origin and a lack of global model support for genesis were probably significant reasons for the poor official forecasts of Henri's development.

Track

A verification of NHC official track forecasts for Henri is given in Table 5a. Official track forecast errors were lower than the mean official errors for the previous 5-yr period at the 36-through 60-h forecast intervals, but greater than the long-term averages at all other forecast intervals. The climatology and persistence forecast errors (OCD5) were greater than average at all intervals, which is perhaps not surprising since Henri moved on an unusual track, and the high OCD5 errors suggested more difficult than normal track forecasts. The official forecasts (Fig. 6) made during the earlier portion of Henri's existence, through 1200 UTC 19 August, had a right bias and failed to show the center reaching the coast of New England. Later on, most of the official forecasts made after 1200 UTC 20 August exhibited a left bias and took Henri too far west and over Long Island.

A homogeneous comparison of the official track errors with selected guidance models for Henri is given in Table 5b. The consensus guidance, TVCA, TVCX, and TVDG all had lower mean errors than the official forecasts at 12 through 120 h. Among the individual models, the U.K. Met. Office model (EGRI), was one of the best, if not the best, performer at all forecast intervals, and had comparable or lower mean errors than the official forecasts at all intervals. The HWRF and HMON models also did well at most forecast intervals.

Intensity

A verification of NHC official intensity forecasts for Henri is given in Table 6a. Official intensity forecast errors were below the mean official errors for the previous 5-yr period at 12 through 60 h, and higher than the long-term means at 72 through 120 h. A homogeneous comparison of the official intensity errors with selected guidance models is given in Table 6b. The simple and corrected consensus models had mean errors that were mostly lower than the official forecasts at all forecast intervals, and DSHP and LGEM were also good performers. In general,

the official forecasts (Fig. 7) called for Henri to be a hurricane at landfall in the northeast U.S., which turned out to be incorrect.

Storm Surge Forecasts and Warnings

Storm surge watches and warnings associated with Henri are given in Table 7 and illustrated in Fig. 8. A Storm Surge Watch was first issued for portions of the coasts of New York, Connecticut, Rhode Island, and Massachusetts at 0900 UTC 20 August for the possibility of significant storm surge inundation. Portions of the watch area were then upgraded to a Storm Surge Warning at 2100 UTC 20 August. Storm surge inundation of 3 ft or greater above normally dry ground (which NHC uses as a first-cut threshold for the storm surge watch/warning) occurred within isolated portions of the Storm Surge Warning area (Fig. 6). Only one instrument in the region, a USGS tide gauge at Greenport, New York, recorded a peak water level above 3 ft MHHW, but storm surge simulation hindcasts indicate that at least 3 ft of inundation above ground level occurred along portions of the north shore of Long Island and the coast of Connecticut. Sustained tropical-storm-force winds are estimated to have reached the area where 3 ft or greater above ground level occurred around 1200 UTC 22 August, 51 h and 39 h after the Storm Surge Watch and Warning, respectively, were issued.

The initial storm surge inundation forecast, issued with the Storm Surge Watch at 0900 UTC 20 August, was 3 to 5 ft above normally dry ground somewhere between Watch Hill, Rhode Island, and Sagamore Beach, Massachusetts, including Narragansett Bay, Buzzards Bay, Vineyard Bay, Nantucket Sound, and Cape Cod Bay. At that time, Henri was forecast to make landfall in the vicinity of Rhode Island or southeastern Massachusetts as a category 1 hurricane. By 0300 UTC 21 August, 3 to 5 ft of inundation was forecast to occur farther west along the coasts of Long Island and Connecticut as well, commensurate with a westward shift in Henri's forecast track and the continued expectation of landfall as a category 1 hurricane. Since Henri weakened more than expected during its approach to the coast and made landfall as a tropical storm, the storm surge inundation forecasts ended up being slightly too high, with observations and poststorm model simulations suggesting that the peak inundation was 3 to 4 ft above normally dry ground.

Wind Watches and Warnings

Wind watches and warnings associated with Henri are given in Table 8. A Hurricane Watch was issued at 0900 UTC 20 August and a Hurricane Warning was issued at 2100 UTC 20 August for a portion of the northeastern U.S. coast. The Hurricane Warning proved to be unnecessary, since Henri was a tropical storm at landfall. However, the Hurricane Watch and Warning provided about 51 and 39 h of lead time, respectively, before the arrival of tropical storm conditions on the coast.

Impact-Based Decision Support Services (IDSS) and Public Communication

The National Hurricane Center (NHC) began communication with emergency managers on 18 August when Henri was a tropical storm southwest of Bermuda through its landfall in Rhode

Island on 22 August. This communication included briefings with FEMA Headquarters and FEMA Regions 1 and 2, as well as briefings for New York, New Jersey, New York City and the Region 1 states. These decision support briefings were coordinated through the FEMA Hurricane Liaison Team, embedded at the NHC.

The NHC television media pool was activated on 21 and 22 August, and provided a total of 65 media briefings on Henri and its potential impacts on those days.

ACKNOWLEDGMENTS

Much of the observed data in this report came from Post Tropical Cyclone Reports issued by NWS Weather Forecast Offices (WFOs) in Norton, Massachusetts, Upton, New York, and Albany, New York. Data was also provided by the NOAA National Data Buoy Center, NOS Center for Operational Oceanographic Products and Services (CO-OPS) and the USGS.

John P. Cangialosi produced the track map. David Roth of the NOAA Weather Prediction Center produced the rainfall map. Matthew Green and Tiffany O'Connor provided the IDSS briefing information, and Dennis Feltgen provided the media briefing summary.

- ^a Date/time is for sustained wind when both sustained and gust are listed.
- ^b Except as noted, sustained wind averaging periods for C-MAN and land-based reports are 2 min; buoy averaging periods are 8 min.
- ^c Storm surge is water height above normal astronomical tide level.
- ^d For most locations, storm tide is water height above the North American Vertical Datum of 1988 (NAVD88). Storm tide is water height above Mean Lower Low Water (MLLW) for NOS stations in Puerto Rico, the U.S. Virgin Islands, and Barbados.
- ^e Estimated inundation is the maximum height of water above ground. The height of the water above Mean Higher High Water (MHHW) is used as a proxy for inundation, and the wave-filtered water level data was used for USGS instruments.

Table 4.Number of hours in advance of formation associated with the first NHC Tropical
Weather Outlook forecast in the indicated likelihood category. Note that the timings
for the "Low" category do not include forecasts of a 0% chance of genesis.

	Hours Befo	ore Genesis
	48-Hour Outlook	120-Hour Outlook
Low (<40%)	18	18
Medium (40%-60%)	0	0
High (>60%)		

Table 5a. NHC official (OFCL) and climatology-persistence skill baseline (OCD5) track forecast errors (n mi) for Hurricane Henri, 15–23 August 2021. Mean errors for the previous 5-yr period are shown for comparison. Official errors that are smaller than the 5-yr means are shown in boldface type.

Figure 1. Best track positions for Hurricane Henri, 15–23 August 2021. Track over the United States is partially based on analyses from the NOAA Weather Prediction Center.

Figure 2. Selected wind observations and best track maximum sustained surface wind speed curve for Hurricane Henri, 15–23 August 2021. Aircraft observations have been adjusted for elevation using 90%, 80%, and 80% adjustment factors for observations from 700 mb, 850 mb, and 1500 ft, respectively. Dropwindsonde observations include actual 10 m winds (sfc), as well as surface estimates derived from the mean wind over the lowest 150 m of the wind sounding (LLM). Advanced Dvorak Technique estimates represent the Current Intensity at the nominal observation time. SATCON intensity estimates are from the Cooperative Institute for Meteorological Satellite Studies. Dashed vertical lines correspond to 0000 UTC, and solid vertical lines correspond to landfalls.

Figure 3. Selected pressure observations and best track minimum central pressure curve for Hurricane Henri, 15–23 August 2021. Advanced Dvorak Technique estimates represent the Current Intensity at the nominal observation time. SATCON intensity estimates are from the Cooperative Institute for Meteorological Satellite Studies. KZC P-W refers to pressure estimates derived using the Knaff-Zehr-Courtney pressure-wind relationship. Dashed vertical lines correspond to 0000 UTC, and solid vertical lines correspond to landfalls.

Figure 4. Maximum water levels measured from NOS tide gauges (circles) and USGS water level and wave height sensors (squares) during Hurricane Henri. Water levels are referenced as feet above Mean Higher High Water (MHHW), which is used as a proxy for inundation (above ground level) on normally dry ground along the immediate coastline.

Figure 5. Henri rainfall totals (inches). Figure courtesy of David Roth, NOAA Weather Prediction Center.

Figure 6. Official track forecasts for Hurricane Henri from 0000 UTC 16 August to 0000 UTC 23 August. The best track is shown in white.

Figure 7. Official intensity forecasts (kt) for Hurricane Henri from 0000 UTC 16 August to 0000 UTC 23 August. The best track intensity (kt) is shown in white.

Figure 8. Maximum water levels measured during Hurricane Henri from tide gauges (circles) and USGS water level sensors (squares), and areas covered by storm surge watches (lavender) and warnings (magenta). Water levels are referenced as feet above Mean Higher High Water (MHHW), which is used as a proxy for inundation (above ground level) on normally dry ground along the immediate coastline. Black markers denote water levels less than 3 ft above ground level, and white markers denote water levels 3 ft or higher above ground level.
